

BACKEND WORKFLOW

A **backend workflow** is the step-by-step process that happens on the server side of an application after a user performs an action in the frontend (website/app).

For a Java backend developer role, the workflow usually looks like this:

1. User sends a request from frontend
Example: Login button clicked.
2. Request reaches Backend API
Usually handled using frameworks like Spring Boot.
3. Controller receives the request
The controller checks the endpoint and request data.
4. Service layer processes logic
Business logic is written here.
Example:
 - Validate user
 - Calculate data
 - Apply rules
5. Database interaction
Backend communicates with databases like:
 - MySQL
 - PostgreSQLusing:
 - Hibernate
 - JPA
6. Response is generated
Backend sends JSON/data back to frontend.
7. Frontend displays result
User sees success message/data.

Typical backend workflow architecture:

Frontend → API → Controller → Service → Repository → Database

In a Java Spring Boot project:

- Controller → handles requests
- Service → business logic
- Repository → database queries
- Entity → database tables/models

Example workflow for login:

User Login → Backend receives email/password → Checks DB → Verifies password → Generates token/session → Sends success response.

Common backend tools/technologies:

- [Spring Boot](#)
- [Hibernate](#)
- [Postman](#)
- [MySQL](#)
- [Docker](#)
- [Apache Maven](#)

Simple backend workflow diagram:
